* I am acquainted with only one other species closely allied to this, it is as yet undescribed and is labelled in my collection "Aenyclonycha pulvinosa, Reiche, India bor;" it has the same appearance as *L. stridulans*, and has, like it, the epipleural line finely crenulate, but it differs considerably in the structure of the antennæ and of the claws; in *Lachnostenra stridulans*, the flabellum of the antenna is rather long, and composed of five joints, the first is, however, very short, not half the length of the second, which itself is a good deal shorter than the three following ones; the claws are divided into two rather divergent portions of equal length. In the undescribed Reichean species the flabellum is short and composed only of three joints, and the claws of the feet are strongly dentate in the middle.

I add a short diagnosis of this insect.
